## DIGITAL SIGNATURES

---

## DIGITAL SIGNATURES: SYNTAX AND CORRECTNESS I

A signature scheme  $\Sigma$  consists of three PPT algorithms ( $\text{KeyGen}$ ,  $\text{Sign}$ ,  $\text{Verify}$ ) such that:

**KeyGen** The key generation algorithm is a randomised algorithm that takes as input a security parameter  $1^\lambda$  and outputs a pair  $(\text{vk}, \text{sk})$ , the **verification key** and **signing key**, respectively.

- We write  $(\text{vk}, \text{sk}) \leftarrow \text{KeyGen}(1^\lambda)$ .

**Sign** The signing algorithm takes as input a signing key  $sk$ , a message  $m$  and outputs a signature  $\sigma$ . The signing algorithm may be randomised or deterministic.

- We write  $\sigma \leftarrow \text{Sign}(sk, m)$ .
- We may write  $\sigma \leftarrow \text{Sign}(sk, m; r)$  to unearth the used randomness explicitly.

**Verify** The verification algorithm takes as input a verification key  $\text{vk}$ , a signature  $\sigma$  and a message  $m$  and outputs a bit  $b$ , with  $b = 1$  meaning the signature is valid and  $b = 0$  meaning the signature is invalid. Verify is a deterministic algorithm.

- We write  $b \leftarrow \text{Verify}(\text{vk}, \sigma, m)$ .

## DIGITAL SIGNATURES: SYNTAX AND CORRECTNESS IV

We require that except with negligible probability over  $(vk, sk) \leftarrow \text{KeyGen}(1^\lambda)$  and potentially the randomness used in  $\text{Sign}$  that:

$$\text{Verify}(vk, \text{Sign}(sk, m), m) = 1 \text{ for all } m.$$

## DIGITAL SIGNATURES: WHAT SHOULD THEY DO?

What do you think should be the security goal of a digital signature scheme?

## DIGITAL SIGNATURES: SECURITY ((E/S)UF-CMA, TRADITIONAL)

“... unforgeability under chosen message attacks”

(E/S)UF-CMA	$S(m)$
1 : $\mathcal{Q} \leftarrow \emptyset;$	1 : $\sigma \leftarrow \Sigma.\text{Sign}(\text{sk}, m)$
2 : $\text{vk}, \text{sk} \leftarrow \Sigma.\text{KeyGen}(1^\lambda);$	2 : $\mathcal{Q} \leftarrow \mathcal{Q} \cup \{(m, \sigma)\}$
3 : $(m^*, \sigma^*) \leftarrow \mathcal{A}^S(\text{vk});$	3 : <b>return</b> $\sigma$
4 : $\text{sig}_\checkmark \leftarrow \Sigma.\text{Verify}(\text{vk}, \sigma^*, m^*) = 1$	
5 : <b>return</b> $\text{sig}_\checkmark \wedge (m^*, \cdot) \notin \mathcal{Q}$ // EUF-CMA: “existential”	
6 : <b>return</b> $\text{sig}_\checkmark \wedge (m^*, \sigma^*) \notin \mathcal{Q}$ // SUF-CMA: “strong”	

$$\text{Adv}_{\mathcal{A}, \Sigma}^{(\text{e/s})\text{uf-cma}}(\lambda) := \Pr[(\text{E/S})\text{UF-CMA}_\Sigma^{\mathcal{A}}(\lambda) \Rightarrow 1]$$

## INDISTINGUISHABILITY-BASED DEFINITION

SUF-CMA	$S(m)$	$V(m, \sigma)$
1 : $\mathcal{Q} \leftarrow \emptyset;$	1 : $\sigma \leftarrow \Sigma.\text{Sign}(\text{sk}, m)$	1 : <b>if</b> $b = 1$ <b>then</b>
2 : $b \leftarrow \{0, 1\}$	2 : $\mathcal{Q} \leftarrow \mathcal{Q} \cup \{(m, \sigma)\}$	2 : <b>return</b> $\Sigma.\text{Verify}(\text{vk}, \sigma, m)$
3 : $\text{vk}, \text{sk} \leftarrow \Sigma.\text{KeyGen}(1^\lambda);$	3 : <b>return</b> $\sigma$	3 : <b>else</b>
4 : $b' \leftarrow \mathcal{A}^{S, V}(\text{vk});$		4 : <b>return</b> $(m, \sigma) \in \mathcal{Q}$
5 : <b>return</b> $b = b'$

## CRYPTOGRAPHIC ASSUMPTIONS

---

# SANDCASTLES?

'Cryptographers seldom sleep well' (Silvio Micali). Their careers are frequently based on very precise complexity-theoretic assumptions, which could be shattered the next morning. A polynomial time algorithm for factoring would certainly prove more crushing than any paltry fluctuation of the Dow Jones." — Joe Kilian. **Founding Cryptography on Oblivious Transfer.** In: *20th ACM STOC*. ACM Press, May 1988, pp. 20–31. DOI: [10.1145/62212.62215](https://doi.org/10.1145/62212.62215)

- 1997** Gödel Prize
- 2004** RSA Award for Excellence in Mathematics
- 2007** Member of the National Academy of Sciences
- 2007** Fellow of the IACR
- 2012** Turing Award
- 2017** ACM Fellow

# CRYPTOGRAPHIC PRIMITIVES

## Symmetric Primitives

- Block and stream ciphers (AES, ChaCha20, ...)
- Authentication codes (HMAC, Poly1305, ...)
- Hash functions (SHA-2, SHA-3, ...)

## Asymmetric Primitives

- Key agreement and public-key encryption (RSA, DH, ECDH, ...)
- Digital signatures (RSA, DSA, ECDSA, ...)

## MINICRYPT VS CRYPTOMANIA

---

# ONE-WAY FUNCTIONS

## Definition (OWF)

A function  $f : \{0, 1\}^n \rightarrow \{0, 1\}^m$  is **one-way** if the following two conditions hold:

1. **(Easy to compute)** There exists a polynomial-time algorithm  $\mathcal{A}_f(x)$  computing  $f$ , i.e.  $\mathcal{A}_f(x) = f(x)$  for all  $x$ .
2. **(Hard to invert)** for every probabilistic polynomial-time  $\mathcal{B}$ , we have:

$$\Pr_{x \leftarrow \{0,1\}^n} [\mathcal{B}(1^n, f(x)) \in f^{-1}(f(x))] < 1/\text{poly}(n).$$

## OWF<sub>f</sub>

- 
- 1:  $x \leftarrow \{0, 1\}^n$
  - 2:  $x' \leftarrow \mathcal{A}^{f(x)}$
  - 3: **return**  $f(x') = f(x)$

## Assumption

We do not know if one-way functions exist!

# ONE-WAY FUNCTIONS IMPLY A LOT

- OWFs  $\Rightarrow$  PRGs<sup>1</sup>
- PRGs  $\Rightarrow$  PRFs<sup>2</sup>
- PRFs  $\Rightarrow$  PRPs<sup>3</sup>
- OWFs  $\Rightarrow$  Digital Signatures (sketch this lecture)
- OWFs  $\xrightarrow{?}$  Key Exchange/Public Key Encryption (unlikely!)

## ONE-TIME DIGITAL SIGNATURES FROM OWFs

- KeyGen  $f(\cdot)$  is a one-way function. Sample random numbers
$$(a_{0,0}, a_{0,1}), (a_{1,0}, a_{1,1}), \dots, (a_{|m|-1,0}, a_{|m|-1,1}).$$

Publish  $f(a_{i,j})$  for all  $a_{i,j}$ .

- **Sign** Let  $b_i$  be the bits of  $m$ . For each bit  $b_i$ , publish  $a_{i,b_i}$ .
- **Verify** Check that  $a_{i,b_i}$  indeed maps to  $f(a_{i,j})$  in the public key.

Leslie Lamport. **Constructing Digital Signatures from a One-way Function**. Technical Report SRI-CSL-98. SRI International Computer Science Laboratory, Oct. 1979

# TOY IMPLEMENTATION

```
from hashlib import sha256
from secrets import token_bytes as U
H = lambda m: sha256(m).digest()

def key_gen():
    sk = [(U(secpar//8), U(secpar//8)) for i in range(secpar)]
    vk = [(H(sk[i][0]), H(sk[i][1])) for i in range(secpar)]
    return vk, sk

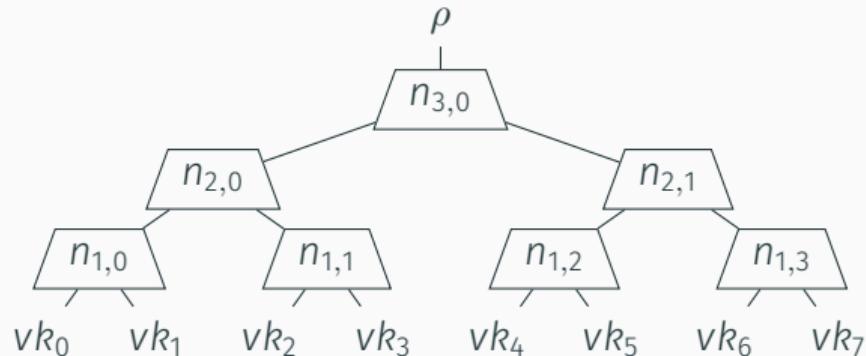

def sign(sk, m):
    sig = []
    for i in range(secpar//8):
        for j in range(8):
            sig.append(sk[8*i+j][(m[i] >> j) % 2])
    return tuple(sig)

def verify(vk, sig, m):
    for i in range(secpar//8):
        for j in range(8):
            assert(vk[8*i+j][(m[i] >> j) % 2] == H(sig[8*i+j]))
    return True
```

```
secpar = 256
vk, sk = key_gen()
m = U(secpar//8)
sig = sign(sk, m)
verify(vk, sig, m)
```

True

# MERKLE TREES

- $n_{1,0} := f(vk_0, vk_1)$  etc.
- publish  $n_{3,0}$  as the  $vk$
- pick a one-time keypair, e.g.  $(vk_0, sk_0)$ , and sign with Lamport to produce  $\sigma$ .
- signature is  $(\sigma, vk_0, vk_1, n_{1,1}, n_{2,1})$

## SPHINCS<sup>+</sup>

SPHINCS<sup>+</sup> is a stateless hash-based signature scheme, which was submitted to the [NIST post-quantum crypto project](#). The design advances the SPHINCS signature scheme, which was presented at [EUROCRYPT 2015](#). It incorporates multiple improvements, specifically aimed at reducing signature size. For a quick overview of the changes from SPHINCS to SPHINCS<sup>+</sup> see the [blog post by Andreas Hülsing](#). The submission proposes three different signature schemes:

- SPHINCS<sup>+</sup>-SHAKE256
- SPHINCS<sup>+</sup>-SHA-256
- SPHINCS<sup>+</sup>-Haraka

These signature schemes are obtained by instantiating the SPHINCS<sup>+</sup> construction with SHAKE256, SHA-256, and

# WHO WOULD DO SUCH A THING?

The screenshot shows the official website of the National Institute of Standards and Technology's Computer Security Resource Center (CSRC). The top navigation bar includes the NIST logo, a search bar, and a menu icon. Below the header, the Information Technology Laboratory and CSRC logos are displayed. A green 'PUBLICATIONS' button is visible. The main content area features a large title 'FIPS 205' and 'Stateless Hash-Based Digital Signature Standard'. Below the title are social media sharing icons (Facebook, X, LinkedIn, Email) and a date published: August 13, 2024. The 'Author(s)' section lists 'National Institute of Standards and Technology'. The 'Abstract' section describes the standard as specifying a stateless hash-based digital signature algorithm (SLH-DSA) used for detecting unauthorized modifications and authenticating signatory identity. It mentions SLH-DSA is based on SPHINCS+, selected for standardization as part of the NIST Post-Quantum Cryptography Standardization process. The 'Keywords' section includes terms like computer security, cryptography, digital signatures, Federal Information Processing Standards, hash-based signatures, post-quantum, and public-key cryptography. To the right, a 'DOCUMENTATION' sidebar provides links to the publication (DOI), download URL, federal register notice, NIST news article, and PQC standardization project. It also lists related NIST publications (FIPS 203, FIPS 204) and document history entries for FIPS 205 (Draft and Final versions).

Date Published: August 13, 2024

**Author(s)**

National Institute of Standards and Technology

**Abstract**

This standard specifies the stateless hash-based digital signature algorithm (SLH-DSA). Digital signatures are used to detect unauthorized modifications to data and to authenticate the identity of the signatory. In addition, the recipient of signed data can use a digital signature as evidence in demonstrating to a third party that the signature was, in fact, generated by the claimed signatory. This is known as non-repudiation since the signatory cannot easily repudiate the signature at a later time. SLH-DSA is based on SPHINCS<sup>+</sup>, which was selected for standardization as part of the NIST Post-Quantum Cryptography Standardization process.

## KEY EXCHANGE FROM OWFs?

- Bob constructs  $n$  puzzles, each being an encryption of two random numbers  $p_i := \text{Enc}(k_i, (x_i, y_i, 0))$ , and sends them to Alice.
- Alice picks a puzzle at random, say  $p_j$ , and brute-forces the decryption.<sup>4</sup>
- Alice encrypts her message using  $y_j$  as the key and sends  $x_j$  along in the clear.
- Bob uses  $x_j$  to identify which  $y_j$  to use for decryption.

Ralph C Merkle. **Secure communications over insecure channels.** In: *Communications of the ACM* 21.4 (1978), pp. 294–299

---

<sup>4</sup>We assume this can be done in  $n$  steps and we assume Alice can decide when she guessed the correct decryption, e.g. by checking that zero is the last entry of the plaintext.

## “KEY EXCHANGE” FROM OWFs

- Cost for Alice and Bob:  $\mathcal{O}(n)$ .
- Cost for an adversary:  $\mathcal{O}(n^2)$ : brute-force many puzzles to find the correct one

## PUBLIC-KEY ENCRYPTION (PKE)

A Public-Key Encryption (PKE) scheme is a triple of PPT algorithms ( $\text{KeyGen}$ ,  $\text{Enc}$ ,  $\text{Dec}$ ) with the following syntax and operation:

**KeyGen** The key generation algorithm is a randomised algorithm taking as input a security parameter  $1^\lambda$  and outputs a public/secret key-pair  $(\text{pk}, \text{sk})$ , the **public key** and the **secret key** respectively.

**Enc** The encryption algorithm is a randomised algorithm taking as input a public-key  $\text{pk}$  and a message  $m$  and outputs an encryption of  $m$  under  $\text{pk}$ .

**Dec** The decryption algorithm is a deterministic algorithm taking as input a ciphertext  $c$  and a secret-key  $\text{sk}$ , and outputs a message  $m$  (or an error message indicating a decryption failure).

We require that except with negligible probability over  $(\text{pk}, \text{sk}) \leftarrow \text{KeyGen}(1^\lambda)$  and potentially the randomness used in  $\text{Enc}$ , that it holds:

$$\text{Dec}(\text{sk}, \text{Enc}(\text{pk}, m)) = m \text{ for all } m.$$

## KEY ENCAPSULATION MECHANISM (KEM)

A Key Encapsulation Mechanism (KEM) is a triple of PPT algorithms ( $\text{KeyGen}$ ,  $\text{Encap}$ ,  $\text{Decap}$ ) with the following syntax and operation:

**KeyGen** The key generation algorithm is a randomised algorithm taking as input a security parameter  $1^\lambda$  and outputs a public/secret key-pair  $(\text{pk}, \text{sk})$ , the **public key** and the **secret key** respectively.

**Encap** The encapsulation algorithm is a randomised algorithm taking as input a public-key  $\text{pk}$  and outputs a key  $k \in \mathcal{K}$  and an encapsulation of  $k$  under  $\text{pk}$ .

**Decap** The decapsulation algorithm is a deterministic algorithm taking as input a ciphertext  $c$  and a secret-key  $\text{sk}$ , and outputs a key  $k$  (or an error message indicating a decapsulation failure).

We require that except with negligible probability over  $(\text{pk}, \text{sk}) \leftarrow \text{KeyGen}(1^\lambda)$  and potentially the randomness used in  $\text{Encap}$ , that it holds:

$$c, k \xleftarrow{\$} \text{Encap}(\text{pk}), \text{Decap}(\text{sk}, c) = k.$$

## IND-CPA OF PKE

IND-CPA <sub>PKE</sub>	C( $m_0, m_1$ )
1: $\text{pk}, \text{sk} \leftarrow \$ \text{KeyGen}(1^\lambda)$	1: <b>if</b> $ m_0  \neq  m_1 $ <b>then</b>
2: $b \leftarrow \$ \{0, 1\}$	2: <b>return</b> $\perp$
3: $b' \leftarrow \mathcal{D}^C(\text{pk})$	3: $c \leftarrow \$ \text{Enc}(\text{pk}, m_b)$
4: <b>return</b> $b = b'$	4: <b>return</b> $c$

Figure 1: IND-CPA Security Game (PKE).

$$\text{Adv}_{PKE}^{\text{ind-cpa}}(\mathcal{D}) = |\Pr[\text{IND-CPA}^{\mathcal{D}} = 1] - 1/2|$$

## IND-CPA OF KEMs

IND-CPA <sub>KEM</sub>	C()
1: $\text{pk}, \text{sk} \leftarrow \text{KeyGen}(1^\lambda)$	1: $k_0 \leftarrow \mathcal{K}$
2: $b \leftarrow \{0, 1\}$	2: $c, k_1 \leftarrow \text{Encap}(\text{pk})$
3: $b' \leftarrow \mathcal{D}^C(\text{pk})$	3: <b>return</b> $c, k_b$
4: <b>return</b> $b = b'$	

Figure 2: IND-CPA Security Game (KEM).

$$\text{Adv}_{KEM}^{\text{ind-cpa}}(\mathcal{D}) = |\Pr[\text{IND-CPA}^{\mathcal{D}} = 1] - 1/2|$$

## PKE $\Leftrightarrow$ KEM

**PKE  $\rightarrow$  KEM** Encrypt a random message.

**KEM+Minicrypt  $\rightarrow$  PKE** Encrypt a key for a symmetric encryption scheme.

# THE POVERTY OF PUBLIC-KEY CRYPTOGRAPHY

# THE POVERTY OF PUBLIC-KEY CRYPTOGRAPHY

The Internet runs on factoring and discrete logarithms

# RIVEST-SHAMIR-ADLEMAN (RSA)

## Factoring

Let  $p, q$  be primes of  $\lambda$  bits. Given  $n := p \cdot q$ , find  $p$ .

## RSA

Let  $n := p \cdot q$  be the product of two  $\lambda$ -bit primes. Let  $e \nmid (p - 1) \cdot (q - 1)$ . Given  $n, e$  and  $c := m^e \bmod n$  for  $m \leftarrow \mathbb{Z}_n$ , find  $m$ .

Ronald L. Rivest, Adi Shamir, and Leonard M. Adleman. A **Method for Obtaining Digital Signatures and Public-Key Cryptosystems**. In: *Communications of the Association for Computing Machinery* 21.2 (Feb. 1978), pp. 120–126.  
DOI: 10.1145/359340.359342

- We'd **like** to say that RSA encryption/decryption is based on factoring, but such a reduction is not known
  - If factoring is easy then RSA is insecure
  - RSA could be insecure and factoring hard<sup>a</sup>
- Rabin encryption ( $\approx$  RSA with  $e = 2$ ) is based on factoring

---

<sup>a</sup>... on a classical computer, we'll get to that shortly

# DIFFIE-HELLMAN (DH)

## Discrete Logarithms

Let  $p$  be a  $\lambda$ -bit prime and let  $g$  be a generator of the multiplicative group  $\mathbb{Z}_p^*$ . Given  $g^a \bmod p$  find  $a$ .

## DH

Let  $p$  be a  $\lambda$ -bit prime and let  $g$  be a generator of the multiplicative group  $\mathbb{Z}_p^*$ . Given  $g^a \bmod p$ ,  $g^b \bmod p$  and  $u$ , decide if  $u = g^{ab}$  or random.

Whitfield Diffie and Martin E. Hellman. [New Directions in Cryptography](#). In: *IEEE Transactions on Information Theory* 22.6 (1976), pp. 644–654. DOI: [10.1109/TIT.1976.1055638](https://doi.org/10.1109/TIT.1976.1055638)

- We'd **like** to say that the DH key exchange is based on discrete logarithms, but such a reduction is not known
  - If discrete logs are easy, DH is insecure
  - DH could be easy and discrete logarithms hard<sup>a</sup>

---

<sup>a</sup>... on a classical computer, we'll get to that shortly

## DIFFIE-HELLMAN (DH)

- We didn't use any properties of  $\mathbb{Z}_p^*$  except that it is a group where discrete logarithms are hard.
- Elliptic curves are also groups where it is believed to be hard to compute discrete logarithms<sup>6</sup>
  - Indeed, it is believed only generic algorithms apply, in contrast to  $\mathbb{Z}_p^* \Rightarrow$  much smaller parameters
  - Elliptic curves are usually written additively and not multiplicative.

---

<sup>6</sup>on a classical computer ...

# DIFFIE-HELLMAN (DH)

## Discrete Logarithms

Let  $p$  be prime and let  $g$  be a generator of the multiplicative group  $\mathbb{Z}_p^*$ . Given  $g^a \bmod p$  find  $a$ .

## DH

Let  $p$  be prime and let  $g$  be a generator of the multiplicative group  $\mathbb{Z}_p^*$ . Given  $g^a \bmod p$ ,  $g^b \bmod p$  and  $u$ , decide if  $u = g^{ab}$  or random.

## Discrete Logarithms

Let  $\mathcal{G}$  be a group of order  $p$  and let  $G$  be a generator of  $\mathcal{G}$ . Given  $a \cdot G$  for  $a \in \mathbb{Z}_p$  find  $a$ .<sup>a</sup>

## DH

Let  $\mathcal{G}$  be a group of order  $p$  and let  $G$  be a generator of  $\mathcal{G}$ . Given  $(G, a \cdot G, b \cdot G, U)$  for  $a, b \in \mathbb{Z}_p$  decide if  $U = a \cdot b \cdot G$  or random in  $\mathcal{G}$ .

---

<sup>a</sup>Here,  $a \cdot G$  means to add  $G$  to itself  $a$  times.

# QUANTUM COMPUTERS

- A quantum computer makes use of quantum effects (superpositions and entanglement) to perform computations.
  - Quantum computers are not **faster** than classical computers, they are **different**.
  - Some computations are easy on a quantum computer that are – as far as we know – hard on a classical computer.
- 
- Small universal quantum computers exist.
  - Key challenge is to scale them up by making them more stable.
  - There is a critical point where we can scale up further using error correction.

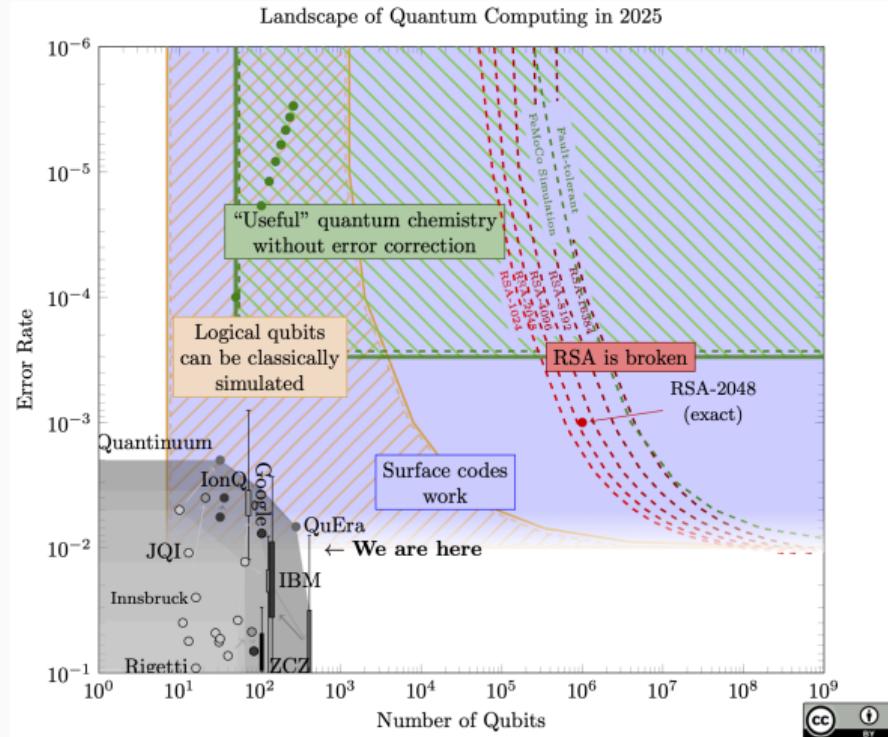

The screenshot shows a news article from the Financial Times website. The header includes the FT logo, a search bar, and navigation links for HOME, WORLD, UK, COMPANIES, TECH, MARKETS, GRAPHICS, OPINION, WORK & CAREERS, LIFE & ARTS, and HOW TO SPEND IT. The main title of the article is "Latest on Quantum technologies". Below the title are three headlines with accompanying images: "A quantum future could be bright if managed well" (with a small robot icon), "Rivals rubbish Google's claim of quantum supremacy" (with a Google 'G' icon), and "Quantum computing builds on Turing's legacy" (with a portrait of Alan Turing). The central article is titled "Google claims to have reached quantum supremacy" and discusses researchers calculating an impossible problem for ordinary machines. It is attributed to Madhurima Murgia and Richard Waters, dated September 20, 2019. The article has 162 comments. At the bottom, there is a summary: "Google claims to have built the first quantum computer that can carry out calculations beyond the ability of today's most powerful supercomputers, a landmark moment that has been hotly anticipated by researchers."

# LANDSCAPE OF QUANTUM COMPUTING IN 2025

## SYMMETRIC PRIMITIVES: QUANTUM COMPUTING PERSPECTIVE (GOOD NEWS)

Best known quantum algorithms for attacking symmetric cryptography are based on Grover's algorithm.

- Search key space of size  $2^n$  in  $2^{n/2}$  operations: AES-256 → 128 “quantum bits of security”.
- Taking all costs into account:  $> 2^{152}$  classical operations for AES-256.<sup>7</sup>
- Assuming a max depth of  $2^{96}$  for a quantum circuit: overall AES-256 cost is  $\approx 2^{190}$ .
- Does not parallelise: have to wait for  $2^X$  steps, cannot buy  $2^{32}$  quantum computers and wait  $2^X/2^{32}$  steps.

“BASED ON VERY PRECISE COMPLEXITY-THEORETIC ASSUMPTIONS, WHICH COULD BE SHATTERED THE NEXT MORNING”

# Polynomial-Time Algorithms for Prime Factorization and Discrete Logarithms on a Quantum Computer\*

Peter W. Shor<sup>†</sup>

## Abstract

A digital computer is generally believed to be an efficient universal computing device; that is, it is believed able to simulate any physical computing device with an increase in computation time by at most a polynomial factor. This may not be true when quantum mechanics is taken into consideration. This paper considers factoring integers and finding discrete logarithms, two problems which are generally thought to be hard on a classical computer and which have been used as the basis of several proposed cryptosystems. Efficient randomized algorithms are given for these two problems on a hypothetical quantum computer. These algorithms take a number of steps polynomial in the input size, e.g., the number of digits of the integer to be factored.

“BASED ON VERY PRECISE COMPLEXITY-THEORETIC ASSUMPTIONS, WHICH COULD BE SHATTERED THE NEXT MORNING”

# POST-QUANTUM STANDARDISATION OF PRIMITIVES

**NIST** Post Quantum Competition Process

**ETSI** Cyber Working Group for Quantum Safe Cryptography

**ISO** WG2 Standing Document 8 (SD8): Survey

**IETF** Standardisation of **stateful** hash-based signatures, nothing further

**CSA** Quantum-safe Security Working Group: position papers

**NIST** Post Quantum Process: Digital Signatures

# POST-QUANTUM STANDARDISATION OF PRIMITIVES

**NIST** Post Quantum Competition Process

**ETSI** Cyber Working Group for Quantum Safe Cryptography

**ISO** WG2 Standing Document 8 (SD8): Survey

**IETF** Standardisation of **stateful** hash-based signatures, nothing further

**CSA** Quantum-safe Security Working Group: position papers

**NIST** Post Quantum Process: Digital Signatures

## Bottom Line

Essentially, everyone was waiting for NIST.

# NIST PQC COMPETITION PROCESS

## Timeline

---

Submission	November 2017
Round 2 Selection	January 2019
Round 3 Selection	July 2020
Winners and Round 4 Selection	July 2022
3/4 Final Standards	August 2024
Additional KEM Standard	March 2025
Final Standard for Falcon	???

---

### “Key Establishment”/Key Encapsulation

- $(pk, sk) \leftarrow \text{KeyGen}()$
- $(c, k) \leftarrow \text{Encap}(pk)$
- $k \leftarrow \text{Decap}(c, sk)$

### Digital Signature

- $(vk, sk) \leftarrow \text{KeyGen}()$
- $s \leftarrow \text{Sig}(m, sk)$
- $\{0,1\} \leftarrow \text{Verify}(vk, s, m)$

# NIST PQC OUTCOME

NIST selected:

**Kyber** A lattice-based KEM (MLWE Problem)

**Dilithium** A lattice-based signature scheme (MSIS/MLWE Problems)

**Falcon** A lattice-based signature scheme (NTRU Problem)

**SPHINCS+** A hash-based signature scheme

**HQC** A code-based KEM (decoding random quasi-cyclic codes)

## “BASED ON VERY PRECISE COMPLEXITY-THEORETIC ASSUMPTIONS, WHICH COULD BE SHATTERED THE NEXT MORNING” (SIKE ATTACK)

Wouter Castryck and Thomas Decru. [An efficient key recovery attack on SIDH \(preliminary version\)](#). Cryptology ePrint Archive, Report 2022/975. 2022. URL:  
<https://eprint.iacr.org/2022/975>

- SIDH was “A decade unscathed” [Cos21]
- SIKE even *lowered* parameters during NIST PQC (following [JS19])
- qualified researchers tried to break it (e.g. [MP19])

### Total Break

All SIKE parameters can be broken in about 2 hours on a single-core laptop now [OP22].

## INTERPRETATION

This was an earthquake.

# "BASED ON VERY PRECISE COMPLEXITY-THEORETIC ASSUMPTIONS, WHICH COULD BE SHATTERED THE NEXT MORNING" (RAINBOW ATTACK)

## Breaking Rainbow Takes a Weekend on a Laptop

Ward Beullens 

IBM Research, Zurich, Switzerland  
[wbe@zurich.ibm.com](mailto:wbe@zurich.ibm.com)

**Abstract.** This work introduces new key recovery attacks against the Rainbow signature scheme, which is one of the three finalist signature schemes still in the NIST Post-Quantum Cryptography standardization project. The new attacks outperform previously known attacks for all the parameter sets submitted to NIST and make a key-recovery practical for the SL 1 parameters. Concretely, given a Rainbow public key for the SL 1 parameters of the second-round submission, our attack returns the corresponding secret key after on average 53 hours (one weekend) of computation time on a standard laptop.

- Rainbow was a NIST finalist<sup>a</sup>
- Can be remedied by increasing parameters, but makes it inefficient

# QKD?

*“Given the specialised hardware requirements of QKD over classical cryptographic key agreement mechanisms and the requirement for authentication in all use cases, the NCSC does not endorse the use of QKD for any government or military applications, and cautions against sole reliance on QKD for business-critical networks, especially in Critical National Infrastructure sectors. [...] NCSC advice is that the best mitigation against the threat of quantum computers is quantum-safe cryptography.”<sup>22</sup>*
